

Analyse comparative des différentes régions de production au Maine

David Yarborough Frank Drummond
Seanna Annis Jennifer D'Appollino

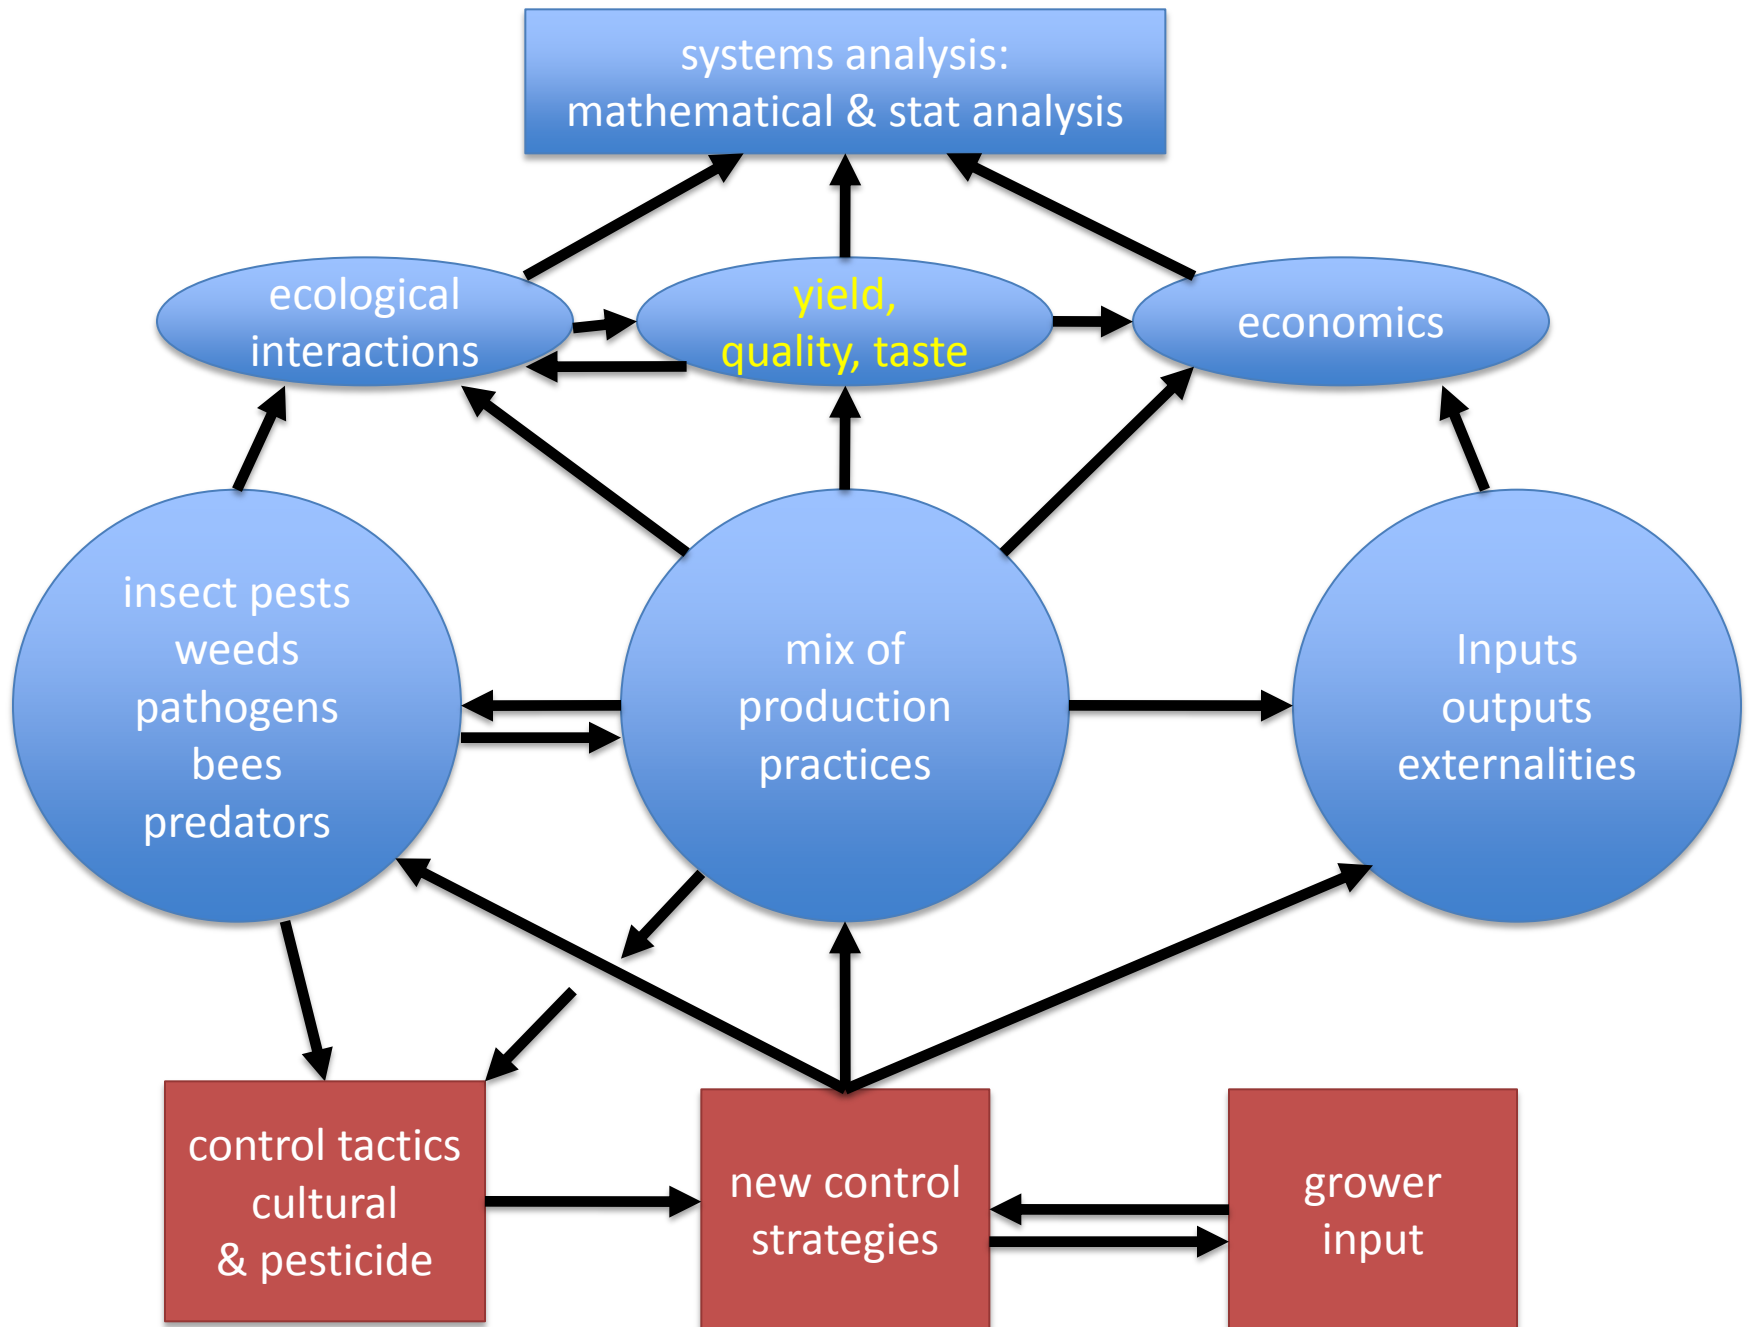

Bleuet 2017 Dolbeau-Mistassini 15 Mars 2017

Wild Blueberries – world wide

Wild production concentrated in Maine, Atlantic Canada and Quebec

Methods - Systems input criteria

	Management input systems overview of inputs 2010 to 2015			
<u>Production Factors</u>	<u>Organic</u>	<u>Low Input</u>	<u>Medium Input</u>	<u>High Input</u>
Pruning	Burned	Burned	Mowed	Mowed
Land leveling	Not land leveled	Not land leveled	Land leveled	Land leveled
pH management	pH managed	No pH management	pH managed	pH managed
Fertility	No fertilizer	Some fertilizer	Fertility (both cycles)	Fertility rate much higher
Pest, disease, and weed control	Cutting woody weeds, grazing with goats, no pesticides used	Herbicides insecticides, some sites with fungicides	Scouting, herbicides, insecticides, fungicides crop year	Scouting, herbicides, insecticides, fungicides in both years
Treatment of bare spots	Mulch	No mulch	No mulch	Mulch
Irrigation	No irrigation	No irrigation	No irrigation	Irrigation as needed
Pollination	Bees 0 to 2 hives/acre	Bees 1-3 hives/acre	Bees 2 hives/acre	Bees 5-7 hives/acre
Harvest method	Hand raked	Hand raked	Mechanical Harvest	Mechanical Harvest

Methods

Structural equation modeling was used to produce a “path analysis” of the dynamics

Initial hypothesized models were based upon our expert opinions and previous observations

Relationships are described by standardized *Beta* or correlation coefficients with the following symbols: †, *, **, and *** representing P value intervals of: ≤ 0.10 , ≤ 0.05 , ≤ 0.01 , ≤ 0.001

Results

Input Systems Study - yield values by system for all years

Results

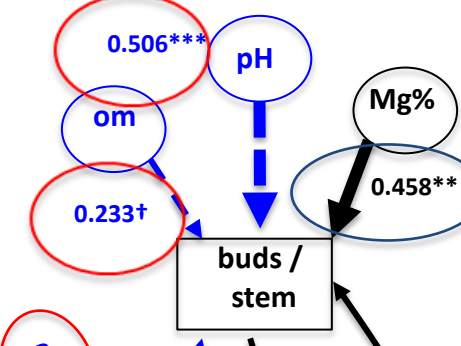

Average Yield by System over Three Crop Cycles

Crop Inputs

crop management

soil environment

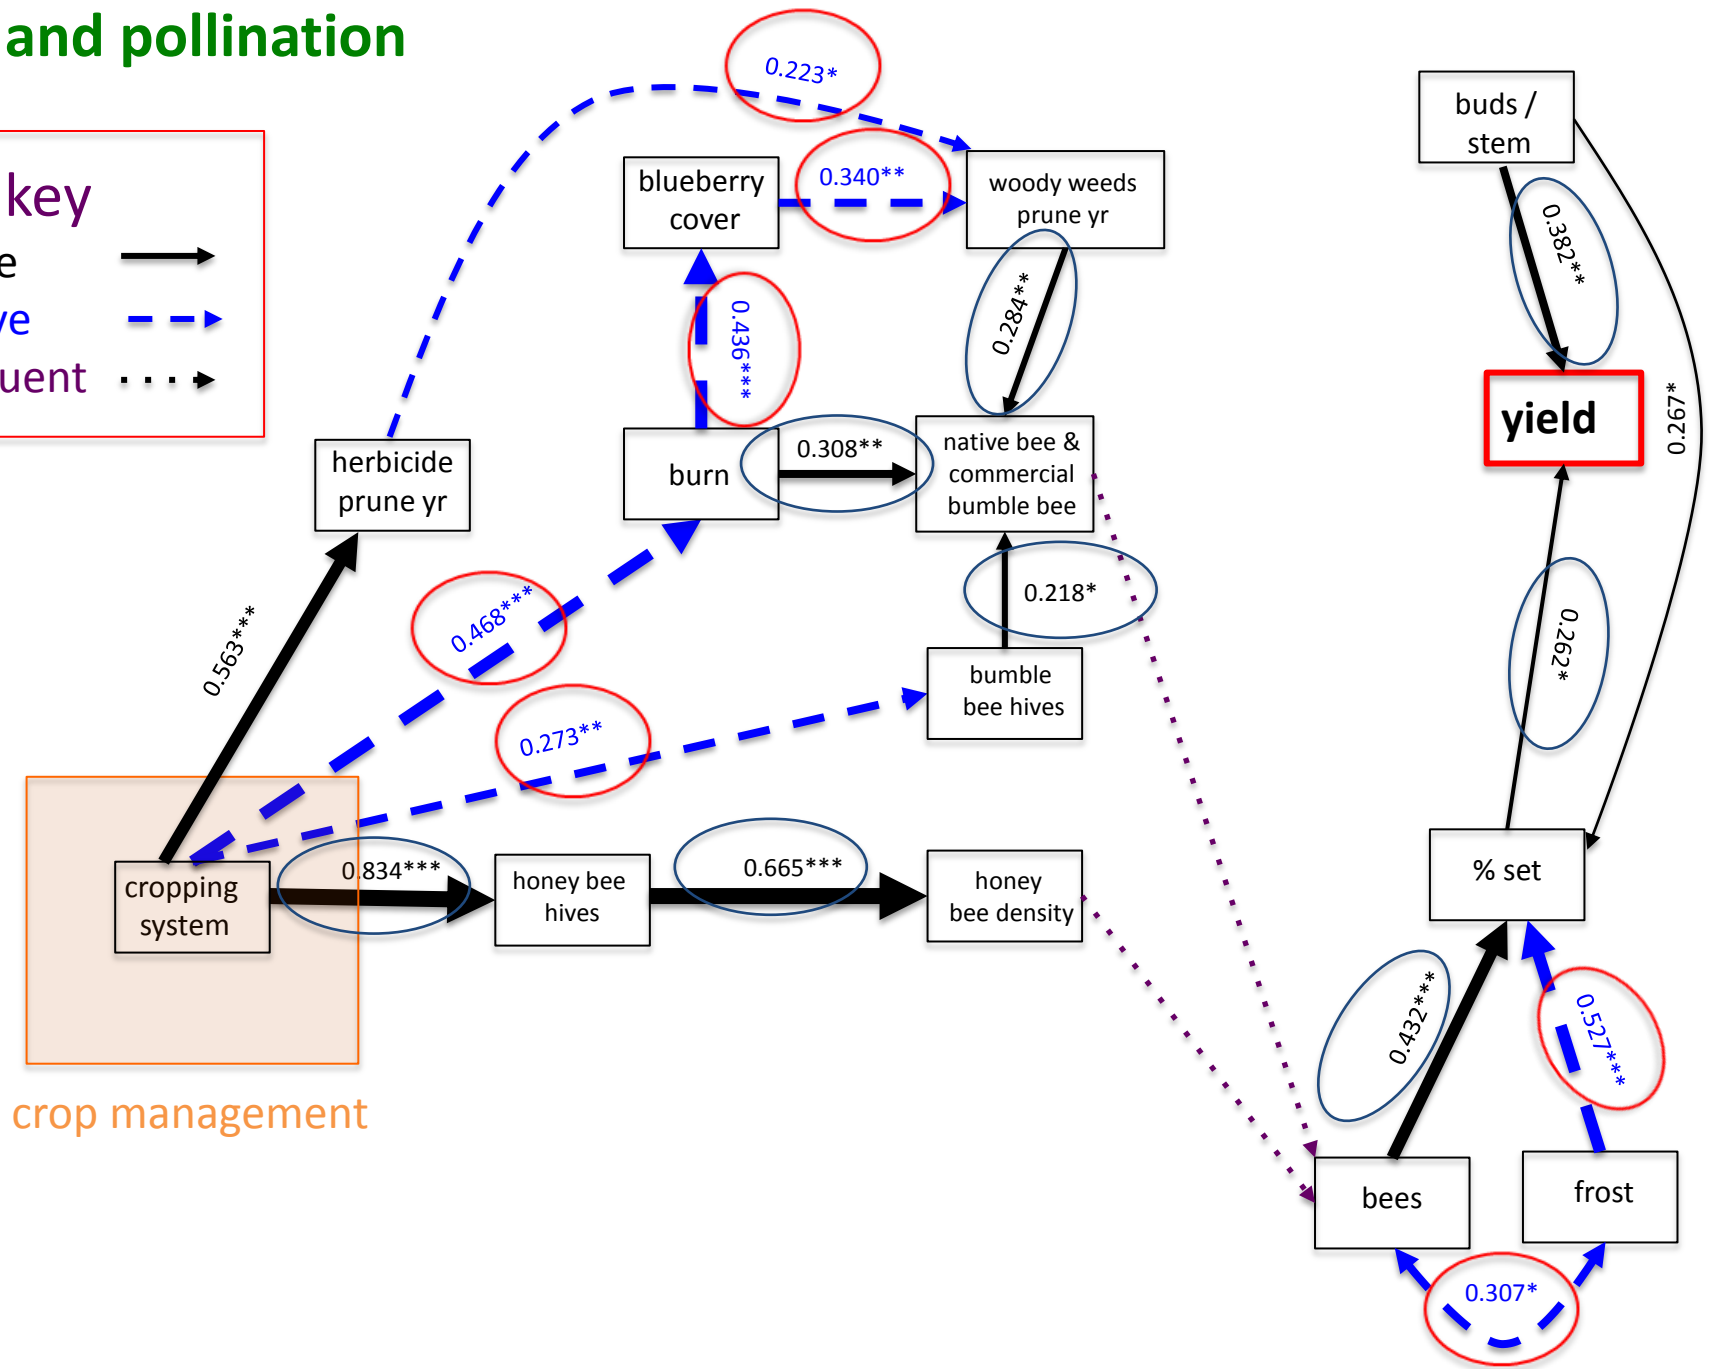

leaf nutrients

frost

bees and pollination

Yield and Profitability from Systems Study

www.organicblueberrytea.com

Conclusion

System management accounted for the greatest variation followed by site and year

Yield for High vs Medium and Low vs Organic system not significantly different but the two groups were significantly different

Key negative factors

Burning for pruning reduced plant stand and yield and Frost major limiting factor to yield

Burning and insecticides decreased beneficial insects but insecticides reduced yield losses

Mummy berry and leaf diseases reduced yield, and bees increased mummy berry

Higher levels of management increased disease and required more fungicides

AI increased stem density and mummy berry

Conclusion

Key positive factors

Number of buds per stem and fruit set were consistently correlated with higher yield

Higher inputs of pollinators major factor in improving yield

Improving plant health with fertilizer and lowering soil pH with sulfur and along with higher organic matter improved yield and leaf B reduced leaf spot

Protecting losses from weeds, insects and disease improved yield

Conclusion

Yield and Profitability

While the organic input production system had low yields, the higher value of the organic fruit and the fresh sales and value added products produced the greatest overall average profit on small scale farms

The medium input system produced the next highest profit a while the high input system was third in profitability

The risk simulation indicated that overall all systems could be profitable but the higher inputs resulted in reduced risk of not being profitable.
